#27 - Boltzmann's thermodynamic<sup>TB</sup> definition of time defines entropy in essentially the same fashion as information theory, and the nominal randomness of heat can be interpreted as maximal information from multiple sources. The earlier idea of a "web" of information that defines the large-scale concept of "how" in time should be identical to this "Boltzmann web" of both thermal and higher level, lower information density (e.g., quantum entanglement) information. The difference is that in the web, Boltzmann's time becomes a far more profound and fundamental
